

Fig.3 Extending analysis of next generation sequencing studies to large numbers of individuals or conditions in the context of a MOD. MOD genome browsers are able to display many tracks of data from e.g. histone mark and transcription factor ChIP studies. However the number of tracks available is growing rapidly and often is already too large to browse effectively. There is a need, for specified experiments, to extract data from regions of interest so that e.g. possible correlations can be examined.
